

Problem statement

EMS (nursing home) employees work under high pressure and time constraints. Their daily task is to provide continuous care for the elderly, while complying with strict rules regarding shifts, rest periods, and workload distribution. Schedule planning is one of the most complex administrative processes: it involves constant adjustments, staff shortages, overlapping shifts, sick leave, urgent replacements, and compliance with legislation.

Understanding the specifics of the EMS schedule

A typical schedule includes morning, afternoon, evening, and night shifts, which often overlap. Each employee must be assigned so that all necessary roles are covered: nurses, assistants, care specialists, night workers.

Additional considerations include:

- individual employee availability
- maximum hour restrictions
- required skills and qualifications
- continuity of resident care
- Primary users
- Non-technical EMS staff: shift supervisors, senior nurses, HR managers.

These people:

- do not have technical training
- work under time constraints
- need the most intuitive interface possible without unnecessary complexity

Key interface limitations

- High information density. Seven days, shifts, employees, and statuses must be displayed on a single screen.
- Limited time for decision-making. The user must be able to see problems instantly.
- Low entry threshold. The interface must be intuitive even without training.
- Many exceptions and conflicts. It is important to show them clearly and unobtrusively.
